Based on a participant request, we examined burnout rates over the past 26 weeks. Preliminary multi-level regression analyses, clustered on participants, revealed that burnout in all 3 domains intensified (up to 0.02 to 0.03 points over the course of each week). Note that these results are similar to the non-clustered results posted last week (a correction was made to last week’s results, see Week #25 Summary Report). We hope you will consider completing follow-up surveys to allow us to better understand how feelings of burnout are changing over the course of the pandemic.

Methods: REDCap online survey was distributed starting May 18, 2020 to primary care professionals and organizations nationally. Recruitment efforts will continue throughout the COVID-19 crisis. Participants can choose to complete the survey once or several times. The survey occurs weekly and is dynamic in order to include pressing questions.

Participants: As of November 24, 2020, we have recruited 850+ participants from all 50 states: 38% physicians, 9% nurse practitioners and physician assistants, 16% nurses, 8% medical assistants, 17% behavioral health providers, 5% non-clinical, an 6% other clinical; 79% of participants are women, 89% white, and the average years working in their current role is 10 years (median; 0.1 to 70 years).
